**CLASS: XII (MATHEMATICS)**

**CHAPTER - 09**  
**TOPIC: DIFFERENTIAL EQUATIONS**  
**HANDOUT: MODULE 3/3**

**Methods of Solving First Order, First Degree Differential Equations:-**

**(3) Linear differential equations:**

A differential equation of the form

$$\frac{dy}{dx} + P y = Q$$

where, P and Q are constants or functions of x only, is known as a first order linear differential equation.

- Examples: (i)  $\frac{dy}{dx} + 2 y = e^{5x}$   
(ii)  $\frac{dy}{dx} + \frac{1}{x} y = \cos x$   
(iii)  $\frac{dy}{dx} + y \sec x = 7$

**Method of solving the first order linear differential equation:**

- (i) Write the given differential equation in the form

$$\frac{dy}{dx} + P y = Q$$

- (ii) Find the Integrating Factor (I.F) =  $e^{\int p dx}$

- (iii) Write the solution formula of the given differential equation as:

$$y \cdot (I.F) = \int Q \cdot (I.F) dx + C$$

which gives the general solution after integration on right hand side.

Example: - (i) Find the general solution of the differential equation

$$\frac{dy}{dx} + 3y = e^{-2x}$$

Clearly this DE is in linear form,  $\frac{dy}{dx} + P y = Q$

$$P = 3, \quad Q = e^{-2x}$$

$$\begin{aligned} \text{I. F.} &= e^{\int p dx} \\ &= e^{\int 3 dx} \\ &= e^{3x} \end{aligned}$$

Solution formula,

$$\begin{aligned} y \cdot (\text{I.F.}) &= \int Q \cdot (\text{I.F.}) dx \\ y \cdot e^{3x} &= \int e^{-2x} \cdot e^{3x} dx \\ &= \int e^x dx \\ &= e^x + C \\ y \cdot e^{3x} &= e^x + C \end{aligned}$$

which is a general solution of the given DE.

Example: - (ii) Find the general solution of the differential equation

$$\text{Cos}^2 x \cdot \frac{dy}{dx} + y = \tan x, \quad \left(0 \leq x < \frac{\pi}{2}\right)$$

The given DE is  $\text{Cos}^2 x \cdot \frac{dy}{dx} + y = \tan x,$

Divide both the sides by  $\text{Cos}^2 x,$

$$\begin{aligned} \frac{dy}{dx} + \frac{y}{\text{Cos}^2 x} &= \frac{\tan x}{\text{Cos}^2 x}, \\ \frac{dy}{dx} + y \text{Sec}^2 x &= \text{Sec}^2 x \cdot \tan x, \end{aligned}$$

Which is a linear DE of the form  $\frac{dy}{dx} + P y = Q$

$$P = \text{Sec}^2 x, \quad Q = \text{Sec}^2 x \cdot \tan x,$$

$$\begin{aligned} \text{I. F.} &= e^{\int p dx} \\ &= e^{\int \text{Sec}^2 x dx} \\ &= e^{\tan x} \end{aligned}$$

Solution formula,

$$\begin{aligned} y \cdot (\text{I.F.}) &= \int Q \cdot (\text{I.F.}) dx \\ y \cdot e^{\tan x} &= \int \text{Sec}^2 x \cdot \tan x \cdot e^{\tan x} dx \end{aligned}$$

Put  $\tan x = t$

$$\sec^2 x \, dx = dt$$

$$y \cdot e^{\tan x} = \int t \cdot e^t dt$$

Integrating by part

$$y \cdot e^{\tan x} = t \cdot e^t - \int e^t dt$$

$$= t \cdot e^t - e^t + C$$

$$y \cdot e^{\tan x} = \tan x \cdot e^{\tan x} - e^{\tan x} + C$$

$$y = (\tan x - 1) + C e^{-\tan x}$$

which is a general solution of the given DE.
